1 Abstract

This document specifies the requirements for the provision of a Metrology Engineer to carry out services relating to metrology activities for ITER machine assembly and plant installation.

2 Background and Objectives

The ITER machine consists of many components, assemblies and associated systems which must be accurately and precisely aligned for the machine to operate. The Machine assembly and Installation (MAI) section is responsible for all aspects of dimensional control from acceptance testing of the constituent parts through to their final operational alignment.

Large volume metrology typically utilises optical measurement systems for dimensional control and alignment. ITER currently plans to use laser trackers, total stations and photogrammetry systems for data capture, interfacing with appropriate software packages for data manipulation and reporting. Currently Spatial Analyzer is the metrology software being used on the project.

Survey networks will be designed, installed, measured and monitored, providing the datum for alignment activities in the various ITER buildings. These networks will enable measurement systems to book into a common coordinate system for alignment tasks anywhere within the applicable building.

The components for ITER are large, heavy and therefore difficult to manipulate. In addition, the restrictive space allocated for their assembly and the exacting tolerances to which they need to be installed puts metrology challenges into perspective.

For the major ITER components, each alignment task shall be carefully studied to develop and qualify the measurement and alignment process. Component reference points will be defined that provide coordinate values linked to the key functional features of the item. Survey geometry shall be defined and registered within the configuration models and measurement simulations will be used to ensure that the process meets the required specification.

3 Scope of Work

The Metrology Engineer will work on studying requirements for alignment of various components and assemblies for the ITER machine. The Engineer will develop and qualify procedures, select suitable measurement systems and compile data packs for execution of the measurement process.

In support of procurement arrangements, the work will cover the review of vendor supplied dimensional control documents, assessment of measurement processes and witnessing of dimensional control surveys. This work will be coordinated with the technical responsible officer for the PA in accordance with the requirements of the ITER Dimensional Metrology Handbook in support of the Alignment and Metrology (A&M) Responsible Officer (RO).

4 Estimated Duration

This contract shall be for a duration of 12 months.
5 Work Description

The metrology engineer shall be expected to take ownership of the alignment/measurement tasks allocated to them, to agree the scope of the activity with A&M RO and to define a plan for its execution. In consultation with the TRO for the system under study, they shall identify the requirements and develop a strategy for implementation.

In many cases the environment in which the measurement tasks are to be carried out will be extremely congested and lines of sight for optical measurement systems very restrictive. The metrology engineer, supported by the design office will evaluate the state of plant foreseen at the time the measurement process will be implemented and develop a process tolerant of the conditions pertaining.

For qualification purposes, where tolerances are very tight or where measurement geometry is difficult, it will be necessary to simulate the measurement process and determine the measurement uncertainty. Spatial Analyzer software is available at ITER to carry out this function representing a wide selection of survey and metrology instruments. This simulation will form part of the design study report.

On completion of the study and qualification work it will be necessary to prepare a procedure to convey the measurement process to the technician carrying out the activity. The procedure shall identify all necessary hardware and software for the task, processes to be followed and outputs required. It will identify all reference data; models, drawings, control files, measurement plans, safety documents etc. collating all data relevant to the task.

For some tasks, bespoke tooling will be required for targeting the component or stationing the metrology instruments. Where this is the case the metrology engineer will manage the design process, prepare technical specifications for procurement and when necessary oversee the manufacturing activity.

The majority of components for the ITER machine are to be supplied by the partners to the ITER agreement through procurement arrangements (PAs). In support of procurement arrangements, the metrology engineer will be required to review procedural documentation and advise TROs on the application of metrology techniques. For factory acceptance of key tokamak components it is planned to place task orders to witness dimensional control surveys at the factories and where necessary to carry out independent surveys. For this activity the metrology engineer will be required to prepare a technical specification for the work package to facilitate tendering and contract placement. The scope of the inspection will need to be defined with the TRO and a data pack detailing processes, datum key features and tolerances shall need to be compiled.

Examples of typical work packages that the metrology engineer could be allocated are detailed below:

5.1 Metrology Lab
The metrology lab, to be constructed within the Assembly Hall, will provide a temperature controlled environment for dimensional control activities. The lab shall contain a coordinate measuring machine large enough to accommodate a blanket shield module plus a selection of metrology instruments to provide a metrology service during the construction of the ITER machine. A study has been completed to establish the scope of operation for the lab and a conceptual layout has been developed. The tasks associated with the next phase are as follows:

- Prepare the Technical Specification for the design, manufacture and installation of the lab
- Oversee the tender process and review submissions
- Oversee the contract through to commissioning
5.2 Preparatory studies and document preparation for tokamak components
Tokamak components are mainly located in the tokamak pit however; some items like the feeders for example span adjacent areas passing through large concrete walls. Typical activities to be carried out in preparation for the assembly of these items are listed below:

- Design specification detailing setting out, dimensional control and alignment requirements, state of plant during alignment activity, schedule etc.
- Dimensional control, pre-alignment and alignment procedures
- Survey simulation to qualify measurement processes
- Inspection report template

This will include items such as cryostat feeders at B2 level, Cryostat toroidal lugs (female), sub-assembly preparation, TF coils and their intercoil connections, VV sectors dimensional control and alignment, thermal shield components alignment and interface customisation etc.

5.3 Metrology Support for Procurement Arrangements
Dimensional control of many of the items provided on procurement arrangements is essential to ensure that they can be assembled to specification at the IO site. To this end, the metrology engineer will be required to assist the A&M RO and the TRO for the PA in areas such as:

- Review dimensional control plans and procedures
- Advise on best practise techniques to be employed
- Carry out survey simulations with Spatial Analyzer to qualify proposed measurement processes from DAs or their suppliers
- Visit DAs and supplier’s factories to assist with the specification and implementation of dimensional control procedures and to witness critical inspections

5.4 Metrology Framework Contracts
The metrology framework contracts are used to prepare and implement the alignment and metrology services for the construction of ITER. The Metrology Engineer will assist the A&M RO in following-up these contracts will; participate in planning activities, develop schedules, prepare specifications for task orders and co-ordinate work execution.

5.5 Metrology Equipment
During construction of the ITER machine and plant systems a wide variety of survey and metrology instruments will be employed. The IO will procure equipment to be utilised by its staff and contract personnel supplied under the framework contracts.

Examples of such equipment include Laser trackers, total stations, digital levels, measurement arms, photogrammetry systems, laser scanners as well as lab based equipment such as a CMM, height gauges, surface tables, gauge blocks hand tools etc.

An assessment of IO requirements will need to be carried out following which a procurement process will need to be launched covering:

- Prepare the Technical Specification
- Oversee the tender process and review submissions
- Receive components, qualify acceptance and oversee installation as required
6 Responsibilities (including customs and other logistics)

Contractor:
The Contractor warrants that the person supplied under the contract has the necessary qualifications and experience to carry out their work. The work is mainly related to establishing and assessing feasibility of measurement and alignment concepts plus associated infrastructure systems. The majority of the work shall be performed on the ITER site because daily exchanges and periodic meetings are foreseen. However, some travel to the countries of the ITER member states is also envisaged.

ITER:
The contractor will work in close collaboration with an ITER nominated engineer. ITER will provide the required information-access to the respective ITER files for executing the work when needed to follow the implementation plan during execution of the work package.

In particular ITER will make available any technical information needed for the contractor to perform the work. All issued / requested documents containing this information must be returned to ITER on completion of the contract.

ITER shall provide a computer with network access rights, an email account and access to Spatial Analyzer software for survey simulation tasks.

7 List of deliverables and due dates (proposed or required by ITER)

Section 5 details typical deliverables for a selection of task types. The generation of these deliverables shall be monitored by the IO engineer during execution of the contract and reviewed at the end of each work package.

8 Acceptance Criteria

Typical deliverables shall be regularly reviewed by IO. The contractor shall update his reports in order to take into account any comments.

9 Specific requirements and conditions

The following attributes are required to carry out the typical work packages identified in this specification:

- University degree in mechanical engineering or surveying, or a combination of qualifications and experience acceptable to IO
- Minimum of 10 years’ experience in the application of industrial measurement techniques appropriate to large volume precision alignment
- Demonstrable expertise in operating Spatial Analyzer:
  - Online interfacing with measurement instruments
  - Offline reporting, data manipulation and survey simulation
- Demonstrable ability to develop innovative solutions to complex survey and metrology tasks.
- Familiarity with the application and operation of portable 3-dimensional measurement systems utilising instruments such as theodolites, total stations, laser trackers, photogrammetry etc.
- Knowledge of Quality Assurance systems and their practical application
• Fluent in English both written and oral
• Ability to communicate effectively and to write clear and concise reports in English
• Proficient in the use of Microsoft Office suite of software
• Good interpersonal, communication and organizational skills
• Ability to work independently when required
• Good planning, organisation, communication and negotiation skills
• Good computer skills, usage of databases would be an advantage
• Excellent team player while capable of working independently
• Ability to work effectively in a multi-cultural environment

The metrology engineer shall have survey and alignment experience gained within the field of large scale assembly processes ideally related to a large physics project where alignment requirements are critical. Experience in both construction surveying and industrial metrology would be a distinct advantage.

10 Work Monitoring / Meeting Schedule

The official language of the ITER project is English. Generally, the work shall require the presence of the Contractor’s personnel at the site of the ITER Organization.

Each work package shall commence with a kick-off meeting.
  • A weekly progress meeting shall take place.
  • A short review shall take place at the completion of each work package.
  • Other regular meetings will take place on an ad-hoc basis as deemed necessary

The Contractor shall prepare short minutes of each kick-off, weekly and milestone progress meeting
